CMPE 327 Assignment 2

Lucas Srigley

Student ID: 20289448

GitHub link: https://github.com/lucas-srigley/cisc327-library-management-a2-9448

Table of Implementation Status

Requirement	Function Name	Implementation Status	Missing
R1	add_book_to_catalog()	Complete	Nothing
R2	get_all_books (database function)	Complete	Nothing
R3	borrow_book_by_patron()	Complete	Nothing
R4	return_book_by_patron()	Complete	Nothing
R5	calculate_late_fee_for_book()	Complete	Nothing
R6	search_books_in_catalog()	Comte plete	Nothing
R7	<pre>get_patron_status_report()</pre>	Complete	Nothing

Complete Function Implementation

All functions have been implemented. In R4, the function allows the user to return a book and includes validation checks for invalid patron or book IDs. In R5, the function calculates the late fee for a patron and validates the provided patron and book IDs. In R6, the function allows searching for books, validates empty search terms and search types, and ensures that the search type is either title, author, or ISBN. In R7, the function retrieves the patron status report and displays it in its own "Patron Status" tab, with validation for invalid patron IDs.

Comprehensive Test Suite Development

For most test cases (R1-R6), I had already written complete test cases. There were some cases (R4-R6) that would say "assert success is False" even though there was a valid input because they weren't implemented in Assignment 1. Now, the valid input tests are successful because the functions are implemented so I changed it to "assert success is True". For R7, I had most of the test cases, but I added some additional functionality with the implemented function so there were some additional variable asserts.

AI-Assisted Test Generation

LLM Model: Microsoft 365 Copilot

Prompt

Based on the attached requirements_specification.md, library_service.py, and database.py files, create individual test suites for R1-R7 in pytest. This is the format the tests should follow:

```
import pytest
from library_service import (
   add_book_to_catalog
)
```

```
def test_add_book_valid_input():
    """Test adding a book with valid input."""
    success, message = add_book_to_catalog("Test Book", "Test Author", "1234567890123", 5)
    assert success == True
    assert "successfully added" in message.lower()
```

Follow-up Prompts

• There should be at least 4-5 test cases per requirement, including positive and negative test cases. (It only generated 1 or 2 cases for each)

Outcome

```
import pytest
from datetime import datetime, timedelta
from library_service import (
 add book to catalog,
  borrow book by patron,
 return_book_by_patron,
  calculate_late_fee_for_book,
 search_books_in_catalog,
  get_patron_status_report
from database import init_database, reset_db, insert_book, insert_borrow_record
# Setup
init database()
reset db()

Test-Case Comparison & Analysis

Comparing the Copilot-generated tests to my own, I found that my tests are more thorough and better organized. My test files focus on specific edge cases like empty inputs, overly long strings, and invalid data types. I verified the exact error messages that should appear. For instance, I check for precise messages like "Title is required." rather than just looking for keywords somewhere in the response. This level of detail helps my tests catch more bugs and ensures the system works exactly as intended. My req1_test.py includes 13 separate validation tests, while the AI version only provided around 5 tests for the same requirement with looser assertions using "in message.lower()" (although I did only request 4-5 test cases). I also organized my tests by requirement into separate files with clear naming conventions, making it much easier to understand what each test covers. The AI combined everything into a single file, which is less organized. That said, the AI-generated tests did show some efficiency, like using loops to test exceeding borrowing limits instead of repeating the same code multiple times like I did. Overall, while AI tools can be helpful for generating a starting point, my manual tests cover all the edge cases more comprehensively. I trust my own testing approach more since AI-generated code needs to be carefully reviewed and validated.
